USB to Serial: Is there user-accessible non-volatile memory in this device?

Short answer: NO.

Detailed answer: There is a small EEPROM (2 kbit or less) embedded. This is used for configuration in the production.

The content can be changed by special software, but only changes items like serial number. This is not much of useful information.

The USB-COM PRO devices make use of a small micro controller with 8KB of Flash Memory, which holds firmware programs. If this is cleared/written over, the device becomes useless.
